Product Summary
Intended-Use

The osteomiR™ workflow has been developed to standardize the quantification of selected microRNA biomarker candidates for fracture-risk in postmenopausal and diabetic osteoporosis. The osteomiR™ kit is intended for research-use only, not for diagnosis, prevention or treatment of a disease. The clinical utility of the osteomiR™ kit is currently investigated in clinical trials.

The osteomiR™ kit provides users with a highly standardized method to determine the levels of 11 informative microRNAs in human serum samples. It alleviates the task of selecting and optimizing analytical methods, data pre-processing and data normalization. It provides standardized serum concentrations for microRNAs with a known association to bone cell function, bone remodelling and fracture risk.

The selection of microRNAs for the osteomiR™ kit was based on several clinical discovery studies, which aimed to screen the levels of microRNAs in serum of patients with established primary, secondary or idiopathic osteoporosis.

Based on the findings from these studies, the following list of microRNAs was selected for the osteomiR™ kit:

Workflow Components

The following components are required for the measurement of 11 informative microRNAs and 5 quality controls in human serum samples:

- miRCURY™ RNA Isolation Kit - Biofluids (Exiqon) for RNA extraction
- osteomiR™ test kit for cDNA synthesis and ready-to-use 96-well test plates
- ExiLENT SYBR® Green master mix from Exiqon.

Overview of required components

- miRCURY™ RNA Isolation Kit – Biofluids, 50 rxns
- osteomiR™ test kit, including microRNA panels, spike in and RT reagents, 48 rxns
- ExiLENT SYBR® Green master mix, 2.5 ml (2 boxes required)

This combination of kits enables the measurement of microRNAs in serum in a single day.

The entire workflow consists of three main steps:

1. RNA extraction
2. Reverse transcription to cDNA
3. PCR amplification
Workflow summary

1. RNA extraction (1.5h)
   Extract RNA using the miRCURY™ RNA Isolation Kit – Biofluids from Exiqon

2. cDNA synthesis (1.5h)
   Prepare cDNA using the osteomiR™ kit reagents

3. Prepare PCR Mix
   Dilute cDNA and mix with Exiqon’s Exilent SYBR® Green master mix

4. Real-time PCR amplification (2.5h)
   Distribute PCR mix into wells on the ready-to-use osteomiR™ plate and start qPCR run

5. Data analysis
   Export data for further analysis, data pre-processing, normalization and statistical analysis
Kit Technology

TA\textit{mi}RNA has partnered with Exiqon Inc. (www.exiqon.com) for the manufacturing of the osteomi\textit{R}™ kit. Exiqon’s technology is based on proprietary reagents that have been specifically optimized for the detection of microRNAs. The technology has been adapted for the osteomi\textit{R}™ kit to offer the best performance for circulating microRNA detection.

RNA Extraction

Exiqon’s mi\textit{RCURY}™ RNA Isolation Kit for biofluids provides a rapid method for the isolation and purification of RNA smaller than 1000 nucleotides from serum and plasma. The purification is based on spin column chromatography using a proprietary resin as the separation matrix. Small RNAs are separated from other cellular components such as proteins. The kit is designed to isolate high quality microRNA in amounts sufficient for qPCR analysis using the osteomi\textit{R}™ kit.

**The workflow consists of 5 simple steps:**

1. Lysis of biofluid components
2. Precipitation and removal of proteins
3. Precipitation of RNA using isopropanol and column loading
4. Washing
5. Elution

In the first part of the RNA isolation process, membranized particles/cells are lysed using the provided lysis solution. Proteins are precipitated using the precipitation solution and the supernatant (including RNA) is mixed with isopropanol for precipitation. This solution is loaded onto a spin-column, where a resin binds RNA in a manner that depends on ionic concentrations. Thus, only the microRNA will bind to the column, while the residual proteins will be removed in the flow-through or retained on the top of the resin. The bound microRNA is then washed with the provided wash solutions in order to remove any remaining impurities, and the purified microRNA is eluted with RNase free water.
Reverse Transcription Quantitative PCR Detection

A universal reverse transcription (RT) reaction is performed, as shown in Figure 3 (Step 1), which means that all microRNA species are converted into complementary DNA (cDNA) at the same time. This enables parallel quantitative PCR (qPCR) detection of different microRNA sequences in one cDNA sample using the osteomiRTM test plate.

Universal RT is achieved by first adding a poly-A tail to the mature microRNA template (Step 1). Complementary cDNA is synthesized using a poly-T-primer with a 3’ degenerate anchor and a 5’ universal tag.

During qPCR, the cDNA is then amplified using microRNA-specific and LNA™-enhanced forward and reverse primers using SYBR® Green for detection of double-stranded DNA (Step 2).

**Step 1: Reverse transcription (RT)**

1. microRNA
2. polyA adenylation and addition of RT-primer + ANCHOR
3. binding of RT-primer ANCHOR
4. single stranded cDNA

**Step 2: Real-time PCR amplification**

1. cDNA + SPECIFIC FORWARD PRIMER + SPECIFIC REVERSE PRIMER
2. priming and extension
3. PCR amplification with SYBR® green signal
**LNA™ Technology**

Locked Nucleic Acids (LNA™) are chemically modified nucleotides, which offer substantially increased affinity for its complementary strand, compared to traditional DNA or RNA oligonucleotides. This results in unprecedented sensitivity and specificity and makes LNA™ oligonucleotides ideal for the detection of microRNAs, due to their short length and varying content of G-C and A-T bases. Without LNA™, the heterogeneous hybridization properties could result in unspecific and low efficient primer binding and compromise data quality.

Read more about the technology at [www.exiqon.com/lna-technology](http://www.exiqon.com/lna-technology)

**Storage and Stability**

The osteomiR™ test kit will be shipped on dry ice and **must be store at -20°C**. Under these conditions, all components are stable until the expiry date on the package or vial. Storage and shipping information on RNA extraction kit and SYBR® green mastermix are available on the respective datasheets shipped with the products.
2

Important Pre-Analytical Considerations
Choice of Biofluid

TAmiRNA has used serum throughout its clinical development program for the discovery of microRNA biomarkers for bone quality. Therefore, we recommend to use serum for any experimental study using the osteomiR™ kit. However, the kit has been shown to enable proper detection of osteomiRs also in EDTA-plasma samples.

Pre-analytical Standardization

Conditions during serum or plasma processing might affect the detection of microRNAs using qPCR. Therefore, we strongly recommend to standardize protocols for pre-analytical processing and serum collection. The following points should be incorporated in the pre-analytical study protocols:

- **Patient variation:** ensure overnight fasting prior to blood collection. Circadian rhythm, activity and diet are known to influence the levels of circulating microRNA content in patients.
- **Use standardized needles and serum collection tubes.** We recommend to use 21 gauge needles for blood collection. Ensure that only the specified blood collection materials are used during the entire study.
- **Blood collection must be performed by a person that is well trained and familiar with the study protocol.** Gloves must be worn at all times when handling specimens. This includes amongst others removal of the rubber stopper from the blood tubes, centrifugation, pipetting, disposal of contaminated tubes, and clean-up of any spills. Tubes, needles, and pipets must be properly disposed of in biohazard containers, in accordance with institutional requirements.
- **Universal precautions and OSHA (Occupational Safety and Health Administration) and institutional requirements** (http://www.osha.gov/SLTC/biologicalagents/index.html) should be followed, including gloves, eye protection or working in a biosafety cabinet for blood processing.
• Coagulation and centrifugation protocols for obtaining serum from whole blood must be standardized and followed strictly (see “Serum Collection” on page 19 for more details).

• Hemolysis (visible as red-colored biofluid) must be recorded for all samples used (see “Quality Control” on page 15 for more details on how to detect hemolysis in your samples).

• After thawing of collected serum samples, ensure that samples are kept cool (on ice or 4°C) at all times and avoid frequent freeze-thaw cycles. Low temperature is essential for RNA stability and sample matrix.

• For handling of serum as well as RNA/DNA we strongly advise to use RNase-free filter tips and nuclease-free microcentrifuge tubes with optimized surface properties to prevent adsorption of nucleic acids (“low binding”).

Storage and Stability of Serum, RNA and DNA

All samples should be stored in nuclease-free plastic tubes with minimized absorption rates for nucleic-acids “low binding”. To avoid freeze-thaw cycles the generation of aliquots of serum samples is recommended. We recommend aliquot volumes of 225 µL serum.

Serum, and RNA samples must be stored at -80°C for long term storage and kept on ice at all times during working procedures.

At TAmiRNA, we have successfully used serum samples for microRNA analysis, which have been stored at -80°C for 15 years. In case the kit is intended to be used for serum samples that are older than 15 years, we recommend to conduct a feasibility study to assess the detection rates of microRNAs compared to fresh samples.

Total RNA samples should be stored in nuclease-free low-binding tubes for not more than 6 months prior to analysis.

Undiluted cDNA must be stored at -20°C and can be used for up to 5 weeks after initial storage. Avoid more than 5 freeze/thaw cycles of frozen RNA and undiluted cDNA samples.
Working with RNA

RNases are very stable and robust enzymes that degrade RNA. Before working with RNA, it is recommended to create an RNase-free environment following the precautions below:

- The RNase-free working environment should be located away from microbiological work stations.
- Clean, disposable gloves should be worn at all times when handling reagents, samples, pipettes, disposable tubes, etc.
- It is recommended that gloves are changed frequently to avoid contamination.
- Designated solutions, tips, tubes, lab coats, pipettes, etc. should be prepared for RNA work only.
- All solutions that will be used should be prepared using molecular biology grade nuclease-free water.
- Clean all surfaces with commercially available RNase decontamination solutions.
- When working with purified RNA samples, ensure that they remain on ice.
- Spin down all reaction and sample tubes before opening.
- Use filter barrier pipette tips to avoid aerosol-mediated contamination.

It is recommended to establish and maintain designated areas for PCR setup, PCR amplification, and DNA detection of PCR products, due to the risk of contaminating reagents and mastermixes with amplified DNA.

The isolation of RNA and the reaction steps preceeding real-time PCR should be performed in rooms or areas, which are separated from areas where PCR experiments are performed in order to avoid contamination with amplified DNA. Use separate clean lab coats for RNA sample preparation, cDNA synthesis and when setting up PCR reactions or handling PCR products. Avoid bringing and opening tubes with amplified PCR products into the PCR setup area.
Quality Control

**Synthetic Spike-In Controls**

In general, spike-in controls are used to monitor the efficiency and correct result of every workstep in the experiment. They can be used to identify outliers due to the presence of inhibiting factors or incorrect handling.

Uniform Cq-values obtained for the spike-ins demonstrate successful and homogenous RNA isolation, reverse transcription and qPCR for the samples. Synthetic spike-ins do not reveal the RNA content and quality in the biological sample.

**UniSp4** – The synthetic RNA spike-in “UniSp4” is added to the sample during RNA extraction. It is used to monitor RNA extraction efficiency.

**Cel-miR-39** – The synthetic RNA Spike-In “cel-miR-39” is added to the extracted RNA during reverse transcription into cDNA. It is used as a control for reverse transcription efficiency. It shares the natural microRNA sequence from C. elegans, which is not found in mammalian species. Reverse transcription efficiency is known to introduce the highest technical variance to RT-qPCR data.

**UniSp3** – The synthetic DNA UniSp3 is present at a fixed position on every osteomiR™ test plate. It is used to monitor PCR efficiency and to detect the presence of PCR inhibitors in samples.

The results obtained for all three spike-ins should be carefully analyzed using the osteomiR™ software app. It should be used to identify potential outliers, and to exclude samples from subsequent normalization and statistical analysis. Spike-ins can be used for calibration of Cq-data of informative microRNAs to remove technical variance. More information can be found in technical notes at www.tamirna.com.
**Hemolysis**

Hemolysis can be a major cause of variation in serum/plasma microRNA levels due to contamination with cellular RNA.

The presence of hemolysis should be assessed visually for each sample. In addition, hemolysis can be assessed using the hemolysis-index, which is based on the relative expression of miR-451a-5p compared to miR 23a-3p. An increase in miR-451a-5p relative to miR-23a-3p indicates the presence of hemolysis in human serum or plasma samples. The osteomiRTM App will automatically calculate and report the Hemolysis Index.

Another option to determine hemolysis is the measurement of the absorbance peak of free haemoglobin by assessing free haemoglobin using a spectrophotometer such as NanoDrop™. Human serum or plasma samples are classified as being hemolyzed if the absorption at 414 nm is exceeding 0.2. However, the presence of small amounts of cellular contamination in serum or plasma samples is not readily detectable by visual or spectrophotometric means.

**RNA Yield**

Determination of RNA yield from 200 µL serum is not possible by optical spectrophotometry or NanoDrop™ due to the lack in sensitivity of the method. We therefore recommend to assess RNA yield and extraction efficiency using synthetic spike-in controls. In addition, the entire analytical protocol precisely specifies to fluid volumes throughout the entire workflow (see “Lab Protocol” on page 17). The osteomiRTM kit uses 200 µL serum for RNA extraction and 2 µL RNA for reverse transcription into cDNA. This is the optimum sample input in order to avoid inhibition of the reverse transcription reaction due to inhibitors that are co-extracted with total RNA. Excess amounts of total RNA in the reverse transcription reaction have been shown to lead to a non-linear quantification of microRNAs as well as a poor call rate.

* not required for the osteomiRTM workflow
Consumables and Instruments Not Supplied by TA\textit{miRNA}

- 99 \% Ethanol, pro analysis
- Isopropanol, pro analysis
- RNase-free water
- Nuclease-free PCR tubes
- Nuclease-free, low nucleic acid binding tubes (1.5 mL)
- Nuclease-free, filter pipette tips
- Sealing foils for PCR plates, transparent, suitable for qPCR
- Heating block or PCR cycler
- Vortexer
- Calibrated pipettes
- Centrifuge for $<2$ mL tubes and 96-well plates
- qPCR Cycler: Roche LightCycler® 480 (I or II) or ABI 7900HT

Other qPCR instruments can be supported upon.

Serum Collection

\textbf{The osteomiR™ Workflow requires 200 µL serum.}

Serum collection is ideally performed after overnight fasting in the morning hours between 8 am and 10 am. This can reduce biological variance in miRNA levels due to activity and diet. We recommend to use 21 gauge needles and red top vacutainer tubes (BD vacutainer®) for blood collection.

Filled collection tubes should sit upright after the blood is drawn at room temperature for a minimum of 30 to a maximum of 60 minutes for the clot to form. The red top tubes do not have to be full to be used.
Centrifuge the blood sample at 2,500g for 10 minutes at room temperature in a horizontal rotor (swing-out head). If the blood is not centrifuged immediately after the clotting time (30 to 60 minutes at room temperature), the tubes should be refrigerated (4°C) for no longer than 4 hours.

After centrifuging, the clot is located at the bottom of the tube, and the serum is on top of the clot.

Use a clean pipette and nuclease-free filter tips to transfer the serum (recommendation: do not pour!). Pipette serum into the labeled nuclease-free (1.5 ml) tubes, filling the vials in sequential order. Aliquot volume is recommended to be 225 µL, so that 200 µL can be safely used for RNA extraction. Close the caps on the vials tightly.

This process should be completed within 1 hour of centrifugation.

**Note: Be very careful not to pick up red blood cells when aliquoting. This can be done by keeping the pipet above the red blood cell layer, slow pipetting and leaving a small amount of serum in the tube.**

Check that all aliquot vial caps are secure and that all vials are labeled. Place all aliquots upright in a specimen box or rack in an -80°C or colder freezer. All specimens should remain at -80°C or colder prior to analysis or shipping. The sample aliquots should not be thawed prior to analysis or shipping.

**Protocol**

The RNA extraction has been **standardized to a volume of 200 µL serum** as starting material to ensure high RNA yield and prevent inhibition of downstream PCR applications.

If less than 200 µL serum is available we recommend to fill available serum up to 200 µL total volume using RNase-free water. Keep in mind that lower sample input might lead to a reduced sensitivity and yield.
RNA Extraction

Before getting started ensure that

• Isopropanol, ethanol and 1.5 mL nuclease-free low bind tubes are available.
• Centrifuge is cooled to 4°C for the first 12,000 g for 5 min centrifugation step.
• Afterwards, the centrifuge is warmed to run at room temperature.

This protocol is designed for human serum and has been adapted from miRCURY™ RNA Isolation Kit – Biofluids from Exiqon.

Step 1
Preparation of Wash Solution 2 BF
First time use only

Add 100 mL of >99% ethanol to the supplied Wash Solution 2 BF.

Note: The label on the bottle has a box that should be checked to indicate that the ethanol has been added.

Step 2
Reconstitution of lyophilized spike-in controls (UniSp4 and cel-miR-39)
First time use only

• Spin down vials before use by centrifugation at 3,000 g for 30 sec at room temperature.
• Resuspend the spike-ins by adding 80 µL nuclease-free water.
• Mix by vortexing and spin down. Store on ice for 20 min.
• Mix by vortexing again and aliquot in low bind tubes (20 µL aliquots).
• Store at -20°C.

Step 3
Thaw serum sample

After thawing on ice, centrifuge the samples at 12,000 g for 5 min at 4°C to pellet any debris and insoluble components and to reduce effect of inhibitors/nucleases.

Step 4
Serum lysis

Transfer exactly 200 µL serum to a new 1.5 mL tube. If using less than 200 µL, fill up to 200 µL with RNase-free water. Ensure equal volumes of all samples.

Add 1 µL UniSp4 to 60 µL Lysis solution BF and mix it with the 200 µL serum. Vortex for 5 sec and incubate for 3 min at room temperature.

For multiple samples prepare a mastermix including 5 % extra volume.

Important note: The UniSp4 spike-in must be mixed with the lysis buffer before mixing with the sample – if added directly to the sample it will be rapidly degraded.

cDNA Synthesis

Keep samples, reagents and reactions on ice (or at 4°C) at all time.

**Step 12**
Thaw total RNA

Thaw total RNA (from step 11) on ice.

**Step 13**
Prepare reagents

Thaw 5x reaction buffer and nuclease free water and put on ice. Immediately before use, remove the enzyme mix from the freezer, mix by flicking the tube and place on ice. Spin down all reagents.

**Step 14**
Prepare cDNA synthesis mix

If performing cDNA synthesis on multiple RNA samples, prepare a mastermix including 5% extra volume.

Dispense the cDNA synthesis mastermix into nuclease free tubes and add template RNA in each tube (i.e. for 10 µL cDNA reaction: 8 µL RT mix + 2 µL RNA).

Mix the mastermix and RNA by gentle flicking and spin down.

**Step 15**
Incubate and heat inactivate

Incubate the reaction at 42°C for 60 min.

Heat-inactivate the reverse transcriptase at 95°C for 5 min. Immediately cool to 4°C.

**Step 16**
Storage

Transfer the undiluted cDNA into nuclease-free low bind tubes and freeze at -20°C for up to 5 weeks.
qPCR Amplification

The osteomiR™ test plate contains 16 different miRNA or QC primer sets. Six samples can be measured on one 96-well plate. Two columns are used per sample.

**Figure 5**

PCR amplification
Plate use

---

**Step 17**
Thaw reagents

Thaw cDNA (from step 16) and ExiLENT SYBR® Green master mix (Exiqon) on ice for 15 - 20 minutes. Keep reagents on ice all the time. Before use mix the Master mix by pipetting up and down.

**Step 18**
Mix cDNA with water and qPCR Master mix

Mix 1.8 µL cDNA with 88.2 µL nuclease free water, then add 90 µL SYBR® Green master mix (in total 180 µL). Mix by pipetting up and down, spin down to collect the liquid at the bottom. Repeat this step for all six samples.

**Step 19**
Prepare osteomiR™ plate

Centrifuge the osteomiR™ 96-well plate at 1,500 g for 90 sec, then remove the seal. Add 10 µL reaction mixture (from step 18) (cDNA, NFW, master mix) to each of the 16 wells. Seal the plate with optical sealing.

**Note:** The experiment can be paused at this point, the plate can be stored at +4°C protected from light for up to 16 hours.
Step 20
Perform qPCR

Before running the qPCR, spin plate for 1,500 g for 90 sec. Perform qPCR and melting curve analysis as shown below. Settings have been optimized for the Roche Light Cycler® 480 II instruments.

Data Analysis

A data analysis application (osteomiR™ app) is available for all our customers. Download links will be provided upon purchase of our kits. Please refer to the respective TechNote at our website at www.tamirna.com/TechNotes.
## Troubleshooting

### RNA Isolation

**Poor RNA Recovery**

**Column has become clogged**  
In most cases this can happen when recommended amounts of starting materials were exceeded. For most biofluids this is unlikely to occur. However, because of the variety of biological samples the amount of starting material may need to be decreased below the recommended levels if the column shows signs of clogging. See also “Clogged Column” below.

**An alternative elution solution was used**  
For maximum RNA recovery it is recommended to elute the RNA with the RNase-free water supplied with this kit.

**RNA content**  
The RNA content in serum is low therefore the concentration measurement of the purified RNA (e.g. spectrophotometric or with fluorescent dyes) is not accurately possible. The protocol is optimized using fixed volumes.

### Clogged Column

**Temperature too low**  
Ensure that the centrifuge and solutions remain at room temperature (18 - 25°C) throughout the procedure. Temperatures below 15°C may result in salt precipitates that may clog the columns. If salt precipitation is present, heat the solution to 30°C until completely redissolved and let the solutions cool to room temperature before use.

### Degraded RNA

**RNase contamination**  
RNases may be introduced when working with the samples. Ensure that proper procedures are followed when working with RNA. Please refer to “Working with RNA” at the beginning of this manual.

**Procedure not performed quickly enough**  
In order to maintain the integrity of the RNA, it is important that the procedure be performed quickly.
Improper storage of the purified RNA
For short term storage RNA samples may be stored at -20°C for a few days. It is recommended that samples be stored at -70°C for longer term storage.
Tip! If possible, snap freeze your RNA in liquid nitrogen before storage in the freezer. Avoid repeated freeze/thaw-cycles by freezing aliquots of your RNA.

Enzymes used may not be RNase-free
In order to prevent possible problems with RNA degradation ensure that enzymes used upstream of the isolation process are RNase-free.

RNA does not perform well in downstream applications
Salt or Ethanol carryover
Traces of salt and ethanol from the binding step can interfere with downstream applications. Therefore, Step 6 (Wash) is important for the quality of your RNA sample. To avoid remaining salts please make sure that the RNA bound to the column is washed 3 times with the provided Wash Solution and ensure that the dry spin is performed, in order to remove traces of ethanol prior to elution.

Inhibitors
Some individual serum samples can contain inhibitors. Using spike-ins that control every step of the protocol inhibitors can be easily detected. Samples that contain inhibitors must be excluded from the analysis.

cDNA and qPCR Amplification
Problem
No fluorescent signal is detected during the PCR
Suggestion
Confirm that the PCR setup was correct by checking the signal obtained for the qPCR spike-in control “UniSp3 IPC”.

No fluorescent signal detected during the PCR, but the spike-in “UniSp3 IPC” gives a valid signal.
Check that the filter in the qPCR cycler was set to either SYBR® Green or FAM/FITC
Check that the optical read is at the correct step of the qPCR cycles.
Related Products

TAmiRNA offers two versions of all its research-use kits. The “small” versions enable the analysis of 12 samples and contain two proprietary qPCR detection plates. The “large” versions enable the analysis of 48 samples and contain eight proprietary qPCR detection plates. TAmiRNA also offers research-use kits for novel microRNA biomarkers in cardiovascular disease. Read more about these products at www.tamirna.com.

Further Reading

TAmiRNA has published extensively on circulating microRNAs as biomarkers for age-associated diseases. Below you find a list of publications, which describe the identification and utility of osteomiRs.
